

FLASH CURING

Because of the mysterious tetrahydrocannabinols, I feel that the flash cure method is adequate and offers the advantage of being extremely fast and efficient.

1. Harvest the plants by cutting the stalks at the bottom or uprooting the whole plant.
2. Wrap the harvest in a sheet or blanket so as not to loose any leaves.
3. Bring the crop into the kitchen and proceed to separate the male from the female plants. Further grade your crop by cutting the plant 1/4 of the way from the top. You will now have 4 grades: top female, top male, bottom female, bottom male. Further grade the crop to your own liking if you wish to experiment with different highs.
4. Carefully separate the seeds from the flower clusters. The seeds should be stored in a fairly cool spot to help maintain their fertility.
5. Taking one grade at a time, separate the leaves from the stems and place the leaves loosely into a frying pan, cookie sheet, or on a piece of alluminum foil. Make sure that the leaves are only one layer thick. This will enable each leaf to be flash cured.
6. Turn the oven on to "broil" and adjust the oven rack so that it's in the middle. After the oven has heated, put the leaves in and watch them very carefully. In 30 seconds or so you will see the leaves start to crinkle up from the heat. As soon as you see a little smoke rising from the leaves, GET READY, and let the leaves smoke for a few seconds, then pull them out. If you have used a cookie sheet or aluminum foil be careful that the leaves do not blow off when pulling out. For this reason, a frying pan should be used.

7. Let the leaves sit for a few minutes, enabling them to be completely cured.

8. The leaves should be dry and brittle and easy to break up by rubbing them in your fingers.

After having enjoyed the wondrous effects of pure unadulterated marihuana, you will probably kiss off that black market bullshit and have home-grown happiness year-round.

PRESERVING POT

In tests recently conducted, it has been shown that any product from the Cannabis Sativa plant (Pot-Hashish-Ganja, etc.) will deteriorate when exposed to air, light, heat and moisture. Heat and moisture are by far the most critical factors. The deterioration rate is most rapid in the earlier stages when it will lose about 5% of its potency per month for about 6 months. From this point on it will lose 2% per month until after about 2 years it will have lost most of its potency. This deterioration can be prevented if the drug is stored properly. The ideal means of storage is to freeze the Cannabis in an air-tight bottle or container. If you do not want to store the drug in your freezer, merely store it in an air-tight bottle in a COOL, DRY AND DARK place.

Your head will be rewarded for your extra effort.
